

## Packages

- A *package* allows classes to be grouped together into a single unit which also acts as a scope.
- A class indicates that it is part of a package using the `package` statement (must be the first statement in a source file)
  - `package packageName ;`
- Packages are imported using an `import` statement
  - `import packageName.className ;`
  - `import packageName.* ;`

Packages & Inner Classes

1

---

---

---

---

---

---

---

---

## Packages

- It is also possible to specify the name of a zip file in the CLASSPATH as well as directories containing class files.
- Any class from another package must be imported. for all Java classes this must be done explicitly with the exception of `java.lang`.
- If a class is not defined as part of a package, then it is considered to be part of the unnamed default package.

Packages & Inner Classes

2

---

---

---

---

---

---

---

---

## Mapping Packages to Files

- Package names map to directory names. Each directory contains all the `.class` files for a given package
  - `cs1.examples.stack` would map to `cs1/examples/stack`
  - the relative pathname is then appended to each entry in the CLASSPATH variable to create a full pathname
- Sun's recommended naming convention:
  - `edu.rit.cs.ptt.classes.cs1.examples`

---

---

---

---

---

---

---

---

## Inner Classes

- Inner, or Nested, classes are standard classes declared within the scope of a standard top-level class.
- There are different kinds of inner class
  - nested top-level class
  - member class
  - local class
  - anonymous class

3/14/01

Packages & Inner Classes

4

---

---

---

---

---

---

---

---

## Nested Top-Level Classes

```
class outer {
    private static class NestedTopLevel {
        normal class stuff
    }
    normal class stuff
}
```

- Nested top-level classes are declared static within a top-level class (sort of like a *class* member).
- They follow the same rules as standard classes
  - `private static` classes cannot be seen outside the enclosing class
  - `public static` allows the class to be seen outside

---

---

---

---

---

---

---

---

## LinkedStack2

```
public class LinkedStack2 {
    private StackNode tos = null;

    private static class StackNode {
        private Object data; private StackNode next, prev;

        public StackNode( Object o ) { this( o, null ); }
        public StackNode( Object o, StackNode n ) {
            data = o; next = n;
        }

        public StackNode getNext() { return next; }
        public Object getData() { return data; }
    }

    public boolean isEmpty() { return tos == null; }
    public boolean isFull() { return false; }
    public void push( Object o ) { tos = new StackNode( o, tos ); }
    public void pop() { tos = tos.getNext(); }
    public Object top() { return tos.getData(); }
}
```

Packages & Inner Classes

6

---

---

---

---

---

---

---

---

## Member Classes

- A member class is a nested top-level class that is *not* declared static.
- This means the member class has a `this` reference which refers to the enclosing class object.
- Member classes cannot declare static variables, methods or nested top-level classes.
- Member objects are used to create data structures that need to know about the object they are contained in.

Packages & Inner Classes

7

---

---

---

---

---

---

---

---

## Class5

```
class Class5 {  
  
    private class Member {  
        public void test() {  
            i = i + 10;  
            System.out.println( i );  
            System.out.println( s );  
        }  
    }  
  
    public void test() {  
        Member n = new Member();  
        n.test();  
    }  
  
    private int i = 10;  
    private String "Hello";  
}
```

Packages & Inner Classes

8

---

---

---

---

---

---

---

---

## this Revisited

- To support member classes several extra kinds of expressions are provided
  - `x = this.dataMember` is valid only if `dataMember` is an instance variable declared by the member class, not if `dataMember` belongs to the enclosing class.
  - `x = EnclosingClass.this.dataMember` allows access to `dataMember` that belongs to the enclosing class.
- Inner classes can be nested to any depth and the `this` mechanism can be used with nesting.

Packages & Inner Classes

9

---

---

---

---

---

---

---

---

## this and Member Classes

```
public class EnclosingClass {
    private int i,j;

    private class MemberClass {
        private int i; public int j;

        public void aMethod( int i ) {
            int a = i;                // Assign param to a
            int b = this.i;           // Assign member's i to b
            int c = EnclosingClass.this.i; // Assign top-level's i to c
            int d = j;                // Assign top-level's j to d
        }

        public void aMethod() {
            MemberClass mem = new MemberClass();
            mem.aMethod( 10 );
            System.out.println( mem.i + mem.j ); // is this a bug?
        }
    }
}
```

Packages & Inner Classes

10

---

---

---

---

---

---

---

---

## new Revisited

- Member class objects can only be created if they have access to an enclosing class object.
- This happens by default if the member class object is created by an instance method belonging to its enclosing class.
- Otherwise it is possible to specify an enclosing class object using the `new` operator as follows

```
- MemberClass b =
    anEnclosingClass.new MemberClass();
```

3/14/01

Packages & Inner Classes

11

---

---

---

---

---

---

---

---

## Local Classes

- A local class is a class declared within the scope of a compound statement, like a local variable.
- A local class is a member class, but cannot include static variables, methods or classes. Additionally they cannot be declared `public`, `protected`, `private` or `static`.
- A local class has the ability to access *final* variables and parameters in the enclosing scope.

Packages & Inner Classes

12

---

---

---

---

---

---

---

---

## Local Class Example

```
public class EnclosingClass {
    String name = "Local class example";

    public void aMethod( final int h, int w ) {
        int j = 20; final int k = 30;

        class LocalClass {
            public void aMethod() {
                System.out.println( h );
                // System.out.println( w ); ERROR w is not final
                // System.out.println( j ); ERROR j is not final
                System.out.println( k );
                // System.out.println( i ); ERROR i is not declared yet
                System.out.println( name); // normal member access
            }
        }

        LocalClass l = new LocalClass(); l.aMethod();
        final int i = 10; }

    public static void main() {
        EnclosingClass c = new EnclosingClass(); c.aMethod( 10, 50 ); }}
```

Packages & Inner Classes

13

---

---

---

---

---

---

---

---

---

---

## Anonymous Classes

- An anonymous class is a local class that does not have a name.
- An anonymous class allows an object to be created using an expression that combines object creation with the declaration of the class.
- This avoids naming a class, at the cost of only ever being able to create one instance of that anonymous class.
- This is handy in the AWT.

3/14/01

Packages & Inner Classes

14

---

---

---

---

---

---

---

---

---

---

## Anonymous Class Syntax

- An anonymous class is defined as part of a new expression and *must* be a subclass or implement an interface

```
new className( argumentList ) { classBody }
new interfaceName() { classBody }
```

- The class body can define methods but cannot define any constructors.
- The restrictions imposed on local classes also apply

---

---

---

---

---

---

---

---

---

---

## Using Anonymous Classes

```
import java.awt.*; import java.awt.event.*;import javax.swing.*;

public class MainProg {
    JFrame win;

    public MainProg( String title ) {
        win = new JFrame( title );

        win.addWindowListener(
            new WindowAdapter() {
                public void windowClosing( WindowEvent e ) {
                    System.exit( 0 );
                }
            }
        );
    }

    public static void main( String args[] ) {
        MainProg x = new MainProg( "Simple Example" );
    }
}
```
